track

ABSTRACT: The construction is described and the main characteristics are presented
of spark chambers with large discharge gaps (5 and 10 cm). The working volume (26 -
liters) was filled with commercial argon or neon of VCh (high purity) grade at atmos-
pheric pressure. The direction of the spark corresponded to the direction of the
particle up to 45° inclination angles. The chambers had 100% registration efficiency
in the entire track-inclination angle interval. For the chamber with 5 cm discharge
gap, the error in the determination of the angle was 2.5×10^{-3} radian. V. Tolbuzin.

TITLE: Investigation of the mechanism of operation of track spark chambers

SOURCE: Zh. eksper. i teor. fiz., v. 46, no. 4, 1964, 1228-1239

TOPIC TAGS: particle detector, spark chamber, track spark chamber, glow center, streamer discharge

ABSTRACT: The characteristic of a 100 x 60 x 19 cm operating track chamber have been studied, in which a distinctly new mode of spark chamber operation (called the "track mode") has been realized. A statistical model of the development of the luminous centers is proposed to explain the operation of the track chamber. Experiments have been performed to ascertain the distribution of the discharges from electrode to electrode, their nature, and their dependence on

Card 1/4

ACCESSION NR: AP4031144

the pulse duration. Other characteristics of the track chambers investigated are the number of luminous centers, the widths of the centers, and the rms deviation of the centers from the true trajectory as a function of the delay time between the particle passage and the time of application of the high voltage pulse. The test results agree well with the statistical model proposed. It is emphasized that, along with the grid time resolution, short recovery time, and simplicity of ordinary spark chambers the track spark chamber has isotropic properties which permit the three-dimensional recording of tracks of particles traveling at all angles, individually or in large groups. It is expected that the spark chamber will become a powerful tool for the study of elementary particle interactions.

TITLE: Investigations of track spark chamber working mechanism (Presented by E. L. Andronikashvili, Academician, 14 December 1963)

SOURCE: AN GruzSSR. Soobshcheniya, v. 33, no. 1, 1964, 49-55

TOPIC TAGS: spark chamber, particle trajectory, Wilson chamber, pulse generator, luminous column, mesh electrode

ABSTRACT: An experimental "track" spark chamber which produces the track of a particle analogous to those observed in a Wilson chamber has been described. The chamber is a rectangular cell $100 \times 60 \times 20 \text{ cm}^3$, filled with high purity neon gas at one atmosphere pressure. The stereoscopy of particle tracks is obtained through a mesh electrode charged by a 200 kv potential. An electronic scheme reduces the time lag between the penetrating particle and the high voltage pulse generator trigger in the $1-200 \mu \text{ sec}$ interval. The investigations included the number of luminous columns, the width of the columns, and the root-mean-square

Card 1/2

ACCESSION NR: AP4018351

deviation of the column from the actual trajectory as a function of time-lag between particle penetration and pulse trigger. For $200 \mu\text{sec}$ time lag τ the pulse duration is 5% longer than at lower values of τ . The luminous columns are seen to be distributed very close to the particle tracks and at $\tau = 1 \mu\text{sec}$ the maximum pulse measurement gives a value of 300 Bev/sec. TITLE: Controlled Spark Chamber - A New Instrument for the
Observation of Charged Particle Tracks

PERIODICAL: Pribory i tekhnika eksperimenta, 1961, No.1, pp.39-42

TEXT: The spark chamber takes the form of a number of discharge gaps between conducting plates located in a neon atmosphere. If immediately after the passage of the particle a high-voltage pulse having a length of about 10^{-7} sec is applied to the plates then a localized streamer discharge takes place roughly along the path of the particle. The width of the streamer is 2 to 3 mm and the intensity is sufficient for it to be photographed. Three such chambers have been built and tested. The spark gaps were formed by sets of parallel plates alternately connected to each other. In two of the chambers the assembly was mounted in a glass cylinder with metal plates at each end. In the third chamber the system was mounted in a perspex container. The plates were made of brass (1 to 2 mm thick) and had an area of Card 1/4

20678 X

of Charged Particle Tracks**

11 x 14 cm². The spark gap was 8, 9 and 10 mm respectively. The working gas was neon ("high purity") at a pressure of 1.1 atm. The characteristics of the chamber were investigated using cosmic μ -mesons which passed through 3 rows of Geiger counters (A, B and C, Fig.1) and the spark chamber. The arrangement is shown schematically in Fig.1. The outputs of the three Geiger counters were fed into a coincidence circuit which then triggered the hydrogen thyratron TFW 1-325/16 (TGII 1-325/16) which in turn applies the high-voltage pulse to the plates of the spark chamber. The device is not very dependent on the delay between the coincidence pulse and the high-voltage pulse (in the range 0-12 μ sec) provided rubber seals and other contaminating materials are not present in the apparatus. The chamber has a plateau in the range 6-11 kV/cm. The position of the particle trajectory can be determined to within a few tenths of a mm, while the error in the determination of the direction of motion of a particle as determined by two spark chambers at a distance of 50 cm apart was found to be

Title : Critique of Eccles' hypothesis

Periodical : Fiziol.zhur. 2, 239-243, Mar/Apr 1954

Abstract : Natural science has always been the arena of ideological struggle. This struggle became even more bitter from the moment that the human brain, which created natural science, itself became the object of study. Natural science here comes immediately into conflict with the problem of the relationship between consciousness and matter and between brain and thought. Eccles has attempted to explain this relationship not on the basis of the scientific concept of the world, which is dialectic materialism, but on the basis of dualism or idealism. His hypothesis rejects Marxist philosophical materialism: it is based on an assumption that the principal phenomena can be easily solved from the point of view of spiritualism and religion. Eccles' hypothesis is merely an assumption advanced to support those economic theories which reflect a civilization that exists solely for the benefit of certain classes.

Title : Influence of the respiratory center on the cortex of large hemispheres

Periodical : Fiziol. zhur. 40, 261-268, May/Jun 1954

Abstract : Experiments were conducted on several cats and one rabbit, and several people were subjected to observation in order to verify the assumption that excitation impulses from the respiratory center, diffused along the central nervous system, act upon the cortex of large hemispheres. On the basis of information collected it was concluded that afferent impulses conveyed from periphery to cortex as a result of respiration originate not in the lungs or respiratory muscles, but are controlled by the respiratory center located in the medulla oblongata. It can be assumed that activity of the cortex, its tonicity, and excitability is also controlled by the respiratory center located in the medulla of the brain. Diagrams. Eleven Soviet and two non-Soviet references.

A Meeting With the Biologists of the Transcaucasian Region
(Vstrecha s biologami Zakhavkaz'ya). Joint Session of the Bio-
logical Departments of Two Academies (Ob"yedineniye zashchita
biologicheskikh estestvennykh resursov akademiy).

PERIODICAL:

Voprosy AN GSSR, 1958, Vol. 29, Nr 1, pp. 121-125 (USSR)

ABSTRACT:

At Tbilisi a joint session of the Department for Biological Sciences of USSR and the departments of the AN Gruzii's SAU of Biological and Medical, as well as of agricultural sciences took place. About thirty representatives of several transcaucasian republics were present, as well as a large group of scientists from Moscow and Leningrad. During the congress, which lasted from September 28 to October 3, 3 plenary and 4 sectional sessions took place. The following reports were delivered:
1) I. S. Beritashvili. On the part played by the hemispheres of the cerebrum and the cerebellum in the spatial orientation of animals.
2) S. P. Marikashvili. The thalamic reticular system and the primary reaction of the cerebral cortex of the large hemispheres.
3) A. I. ROYTBAK: Bioelectric Phenomena in the source of conditioned excitations.

ABSTRACTS OF COMMUNICATIONS

ABSTRACTS OF COMMUNICATIONS

trans these anaerobic wastes and shape them (fermentation).

- During the action of unconditioned stimuli, there is a reduction of intensity, resulting from a decrease in the intensity of the primary response.
- Conditioning of unconditioned stimuli produces a change in the intensity of the primary response.
- During the unconditioned stimulation of Ganz and place (Rathlef and Bischel, 1958), there is a change in the amplitude of primary responses in electrical stimulation of Ganz and place (Rathlef and Bischel, 1958). On the basis of their form it is possible in many cases to record the summations. The interpretation of the cortical mechanism can be accepted by means of analogy, projection area, the field of the central sulcus, projection area, even in certain areas of the cortex, the reaction occurs even in the case of an impossible to suppose the presence of different volleys. APPROVED FOR RELEASE: 02

Figure A. 1. Primary responses of the cerebral cortex to sound clicks elicited by electrical stimulation of the mesial granulata nucleus their changes during microstimulation. (From Carrington and Scoville, *Physiol. Rev.*, 1949, 29, 1-100.)

Experiments were performed on unanesthetized cats and dogs; electrodes placed over the acoustic projection area (latency 1.5-2 sec.) and over other cortical areas and implanted into the medial preoptic nucleus (latency 1 sec.) caused brief (recurrent and simultaneous) bursts of vocalization.

In response to click (1-10 per sec.) or to the stimulation of the ipsilateral acoustic projection area (latency 1.5-10 per sec., 0.5 sec., 1 sec.), auditory responses following the first in the sequence were elicited. These responses were recorded from the acoustic projection area of nonhuman animals (see references cited). The stimulation of GPe produced the same results as those produced by stimulation of GPe in cats. When simulating the elements of reflexes in the same way, the same reaction was produced. When stimulating different cortical areas, different reactions were produced.

AUTHORS: Roytbak, A. I., Dedabrishvili, Ts. M. SOV/20-124-4-66/67

TITLE: On the Mechanism of "Active Relaxation" (Sechenov's Phenomenon)
(O mekhanizme "aktivnogo otdykhha" (fenomena Sechenova)).

PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 124, Nr 4, pp 957-960 (USSR)

ABSTRACT: Sechenov found that simple relaxation is less effective on the restoration of the working ability of a fatigued hand than is an equally long period of relaxation during which work is done by the other hand (soc."active relaxation"). Sechenov assumed that during this period the nerve centers are re-charged with energy (Ref 16). Since then many hypotheses for the clarification of this phenomenon have been propounded (Refs 1-11). The investigation under consideration serves the purpose of clarifying the mechanism of Sechenov's phenomenon on the basis of an analysis of the bioelectric functions of the cerebral cortex. Sechenov's experiment was repeated with the simultaneous recording of the work and of the electro-encephalogram (EEG). Figure 1 shows the changes of the EEG. Figure 2 explains the EEG-analysis of the phenomenon of "active relaxation". From the results obtained it can be concluded that during the period of "active relaxation" the forma^{tio}n reticularis (f.r.) of the brain stem is excited. It

Card 1/3

SOV/20-124-4-66/67

On the Mechanism of "Active Relaxation" (Sechenov's Phenomenon)

can be concluded that this excitation forms the basis of the favorable effect of "active relaxation". A longer period of "active relaxation" is less effective than a short one (Ref 17), as in the former case the activating effect abates. This also explains the favorable influence of adrenalin on the working ability (Ref 3). It could be proved that adrenalin that has been introduced into the blood stream excites the f.r. of the brain stem and causes the "activating" reaction of the EEG (Ref 18). Consequently, the mechanism of "active relaxation" consists in the removal of a cortical block (developed during the preceding work), due to an excitation of the formatio reticularis of the brain stem.-There are 2 figures and 22 references, 17 of which are Soviet.

TITLE: On the glial origin of slow negativity of the cortex

SOURCE: AN GruzSSR. Institut fiziologii. Trudy, v. 14, 1965. Sovremennyye problemy deyatel'nosti i stroyeniya tsentral'noy nervnoy sistemy (Present problems of the activity and structure of the central nervous system), 67-87

TOPIC TAGS: dendritic potential, slow negativity, cortical negativity, paired stimulation, tetanic stimulation, CNS, glia, cerebral cortex, cortical activity

ABSTRACT: The dendritic potential (DP)—20—30 msec of negative potential induced by high-intensity stimulation of the cortical surface—is followed by a slow negativity (SN) of unusually long duration, whose origin and significance are unknown. Slow negativity (SN) was investigated in nembutal-narcotized cats. It was found that SN requires more intense stimulation than DP. After a latent period of approximately 15 msec, SN builds up over 50 to 80 msec to a plateau of 2 mv or more, which lasts 300 to 3000 msec. SN can be evoked by stimuli below the SN threshold, repeated at short (5 to 20 msec) intervals. SN reactions to subsequent stimulation are suppressed so long as a first SN reaction is in progress. In form, duration, and reaction to paired and tetanic stimulation, SN resembles the electrotonic dorsal spinal root po-

2

Card 1/2

L 22212-66

ACC NR: AT5024227

O

tentials. Of the EEG components, it most resembles the delta rhythm. SN is weakened or abolished by local strychnine application, but is comparatively resistant to GABA. DP evoked by stimulation of other parts of the cortex is depressed during SN. On the basis of these findings, it is concluded that SN results from depolarization of apical dendrites due to activation of adjacent glia. Intensive stimulation of a complex of cortical neurons is transmitted to oligodendrocytes through neuroglial connections. This is followed by depolarization of the oligodendrocytes, release of chemical substances into glial-neuronal space, and depolarization of apical dendrites. SN thus [DP] does not seem to be a direct post-synaptic process.

TITLE: Method for tube extrusion. Class 49, No. 172601

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 13, 1965, 101

TOPIC TAGS: metal, metal tube, metal extrusion, tube extrusion

ABSTRACT: This Author Certificate introduces a method for tube extrusion from solid ingots. In this method the metal is first divided into several strips which are subsequently welded in the next die. In order to reduce the extrusion pressure, the diameter of the ingot should be smaller than that of the extruded tube. [AZ]

SOURCE: Byulleten' izobreteni i tovarnykh znakov, no. 13, 1965, 102

TOPIC TAGS: tube, metal tube, tube extrusion, extrusion tool, extrusion press

ABSTRACT: This Author Certificate introduces a tool for the extrusion of tubes from solid ingots, i.e., container, mandrel, welding chamber, and die. In order to increase the rigidity of individual tools and ensure their precise position in relation to one another, thereby improving the accuracy of the extruded tubes, the mandrel is rigidly mounted in relation to the container; it carries an internal die and is provided with a central compartment for the ingot. Radial canals connect this compartment with the welding chamber, which is formed between container wall and the mandrel surface. [AZ]

TITLE: An extrusion attachment. Class 49, No. 169985 18

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 7, 1965, 165

TOPIC TAGS: extrusion, panel extrusion, extrusion attachment, panel extrusion device, 14

ABSTRACT: This Author Certificate introduces an attachment for the extrusion of panels from hollow billets. The device consists of a mandrel (see Fig. 1 of the Enclosure) fitted into a hollow stem and centered in the die which, during extrusion, forms the inner wall of the container. In order to lower the extrusion force and to increase the quality of extruded articles, the stem is designed as a cylinder in which the mandrel slides freely and the die has the shape of an open ring. involved the following processes: reduction of oxides by tungsten, vaporization of reduction products, reaction between the reduction products in the vapor phase, and vaporization and dissociation of oxides. The main factor determining the weight loss in the tungsten-refractory oxide system is vaporization of tungsten oxide. The time dependence of weight loss during the reaction between tungsten and aluminum oxide is shown in Fig. 1. The time dependence for tungsten-silicon oxide reaction follows a similar pattern but the weight loss is less intensive. Orig. art. has: 5 figures.

TITLE: On the motion of a gyrocompass whose point of support shifts randomly *B*
0

SOURCE: Prikladnaya matematika i mehanika, v. 29, no. 1, 1965, 165-172

TOPIC TAGS: gyrocompass motion, randomly shifting support, linear inhomogeneous differential equation, random process, integral equation solution

ABSTRACT: The motion of a gyrocompass is analyzed in the case when its point of support shifts randomly. To determine the equations of motion, the general equations of motion derived by A. Yu. Ishlinskii (On the theory of gyrocompasses. Prikladnaya matematika i mehanika, v. 20, no. 4, 1956) are taken. These equations are reduced by means of certain transformations to a new equivalent form. On the basis of these equations, using certain simplifying assumptions for the motion parameters, a system of linear inhomogeneous differential equations with random coefficients and right-hand sides is derived which describes the motion of a gyrocompass when its point of support shifts randomly. In the case when no other external forces are applied to the gyrocompass in addition to the forces explicitly indicated in the general equations of motion, the derived equations of motion are

Card 1/2

L 32113-65

ACCESSION NR: AP5006266

reduced to a simplified integral equation of matrix form. The solution of this equation is obtained by the method of successive substitutions in the form of an absolutely and uniformly convergent series in powers of a small parameter λ . As an example, the motion of a gyrocompass is analyzed in the case when the random processes $W_j(t)$ ($j = 1, 2, 3$), which characterize the acceleration components on the coordinate axes of the point of support, are stationary processes of the white noise type whose mathematical expectations are equal to zero and the correlation functions are of a particular form. $$A(x, D) = \sum_{|\alpha| \leq 2m} a_\alpha(x) D^\alpha.$$

is given. On the manifold $\partial\Omega$ the following operators are determined,

$$B_l(x, D) = \sum_{|\alpha| \leq m} b_{l\alpha}(x) D^\alpha, l=1, \dots, m,$$

$a=(a_1, \dots, a_n)$ is the multiindex, $|\alpha| = \alpha_1 + \dots + \alpha_n$. The functions $a_\alpha(x), b_{l\alpha}(x)$ are assumed to be sufficiently smooth. It is well-known (RZHMAT, 1961, 8B180) that the properly elliptic operator $\mathcal{U} = (A, B)$ in all cases where $l > l_0 = \max(2m, m, +1/2)$ realizes (with accuracy to finite-dimensional spaces) the homeomorphism

$$\mathcal{G}: H^l(\Omega) \rightarrow H^{l-m}(\Omega) \times \prod_{j=1}^{n-l+m} H^{1/2}(\partial\Omega).$$

If, for operator \mathcal{U} , there exists a conjugate operator of the same type, then it may be concluded from considerations of duality that the conjugate operator \mathcal{U}^*
